

Energy management fonafote

Energy management fonafote

Energy costs are rising, consumers are looking for sustainability, and regulations are growing and becoming more comprehensive. All of these make effective energy management important for organizations, from tracking usage to reducing waste. Businesses that focus on smarter energy use position themselves for long-term success, driving efficiency without compromising on operational goals.

Energy management is the process of tracking, controlling, and improving energy usage. At its core, it involves assessing energy consumption patterns and identifying inefficiencies so you can implement strategies to reduce waste-while still keeping operations running smoothly. Some examples of these strategies include:

These ensure that you're using resources responsibly and sustainably. In fact, regular audits for proper energy management have been mandatory since December 5th, 2015. Businesses need to carry them out every four years, to check whether they've successfully reduced energy consumption over time. In the EU, energy audits are regulated according to the DIN EN 16247-1 standard. Commercial energy audits can be an alternative or supplement to certified energy or environmental management systems.

As energy prices rise and sustainability becomes a concern for consumers, organizations must take control of how they consume energy. Here's why energy management matters:

While the situation of each organization varies, there are some best practices that are consistent across industries. Here's how you can improve your organization's energy management:

Commercial energy audits are the foundation of energy management. These examine the amount of energy a building is consuming, and identify anything that's causing unnecessary consumption. In fact, auditors often use checklists during these inspections to make sure they don't miss anything. Over the course of a commercial energy audit, inspectors will use gathered information to recommend energy and cost-saving measures.

It's important to have clear, achievable goals to provide direction for energy management initiatives. You can use the SMART framework-specific, measurable, achievable, relevant, and time-bound--to define your objectives:

You can get fast energy savings by identifying the machines or systems that consume the most energy then upgrading them to be more efficient. For example, you might replace old motors with high-efficiency models, or even add timers or sensors to reduce idle energy use. Another option is to analyze usage patterns to identify ways to shift energy-intensive tasks to off-peak hours, when electricity rates might be lower.

Energy management is at its most successful when everyone in the organization contributes, especially since

small, everyday actions can lead to meaningful savings. Host workshops to teach staff about energy-efficient practices and share practical examples, such as turning off unused equipment. Afterwards, you can show them tangible results-like cost savings or energy contributions-so they're aware of the impact.

Renewable energy sources reduce environmental impact while lowering energy costs over time. These include solar panels, wind turbines, or geothermal systems. You don't have to transition to renewables all at once, though-you can start small, such as purchasing renewable energy credits or installing solar water heaters for certain operations. This also aligns with corporate social responsibility (CSR) goals, enhancing your organization's reputation with customers and stakeholders.

Thorough commercial energy audits help control energy consumption and costs. They're also an important means of documenting essential energy flows and determining potential energy reductions. In order to meet sustainability goals, energy audits are legal requirements in many countries.

In the UK, for example, they're called EPCs and are mandatory in most types of buildings. If a building's energy usage is found inefficient during an inspection, appropriate energy efficiency measures must be implemented. When conducting a commercial energy audit, you should check:
